Abstract—The Internet of Things (IoT) was born in the mid 2010's, when the threshold of connecting more objects than people to the Internet, was crossed. Thus, attacks and threats on the content and quality of service of the IoT platforms can have economic, energetic and physical security consequences that go way beyond the traditional Internet's lack of security, and way beyond the threats posed by attacks to mobile telephony. Thus, this paper describes the H2020 project "Secure and Safe Internet of Things"(SerIoT) which will optimize the information security in IoT platforms and networks in a holistic, cross-layered manner (i.e. IoT platforms and devices, honeypots, SDN routers and operator's controller) in order to offer a secure SerIoT platform that can be used to implement secure IoT platforms and networks anywhere and everywhere.

I. INTRODUCTION

Having its roots in a globally interconnected continuum of RFID (Radio Frequency Identification and Detection)-based technology, the IoT¹ concept has been considerably extended to the current vision that envisages billions of physical things or objects, outfitted with different kinds of sensors and actuators, being connected to the Internet via the heterogeneous access networks enabled by current and future technologies [1]. Currently, IoT is emerging as the next big thing introducing the next wave of innovation with rather endless possibilities. For instance, it opens a huge window of opportunity for the creation of applications (e.g. automation, sensing, machine-to-machine communication, etc.), promises to improve and to optimize our daily life and forms the infrastructure that allows intelligent sensors and smart objects to communicate and work together [2].

Contrary to the application layer of the World Wide Web that was developed on the infrastructure of the Internet (i.e. the physical layer or network made up of switches, routers and other equipment), IoT becomes immensely important because it is the first real evolution of the Internet - a leap that will lead to revolutionary applications that have the potential to dramatically improve the way people live, learn, work, and entertain themselves. Today the IoT is well under way, with the potential for changing people's lives for the better, especially with regard to human safety and security [3]. It has created new application domains and already infiltrated and dominated a wide range of existing ones (e.g. Consumer Automotive, Telecommunications, Home and Building Automation, Data

Center and Cloud, Consumer Devices, Industrial, Medical, Commercial Transportation). So, as Personal Computers (PCs) start to show revenue declines, IoT is rising as the next big wave after PCs, networking and mobile systems. Moreover, based on the "cloud" trend that expects "everything to be connected" to Cloud services, we can also refer to the so-called Internet of Everything (IoE) [4], which represents the open access to data from one or more monitoring and control systems by third-party applications to provide unique, additional value to stakeholders.

In this context, it is a commonplace in the research community and the IoT related industry that challenges in future IoT and IoE will be affected by issues, such as the lack of a shared infrastructure and common standards, the management of (big) data, including control and sharing, security, flexibility, adaptability and scalability, and of course the maintenance and update of the IoT network. While analysts agree that security concerns and the effective management of produced data need to be worked out before the IoT can be fully developed, there is little doubt that the long-range impact will be substantial.

II. SECURITY AND THE IOT

With IoT's arrival, EU industry, homes and society are catapulted into the huge arena of security risks that accompany an untested yet already universal technology that directly manages our cyber-physical reality on a daily, and indeed second by second, way beyond the security issues that are posed by the original machine to machine systems [5], [6] and mobile telephony [7]. But by thinking positively, we see that security threats to the IoT, are also a great opportunity for industry and business, and all those who will know how to harness security science and technology in order to counter the emerging threats in a cost effective manner, so as to market products to support the development of a thriving business that assures the safety and security of the IoT.

While today security technologies can play a role in mitigating risks connected to IoT security [8], we foresee problems and potential threats that are not limited to what has been developed until now. In currently developed systems, the data is not delivered using uniform, consistent technology; often conflicting protocols are used with unverified designs. Moreover, we tend to think of the maintenance cycle in a short term span, which may mean that updates to IoT systems are not compliant. Lack of standards for authentication and

¹From now on, rather than write "the IoT" we shall simply say "IoT".

authorization, as and security standards, as well as standards for platform configurations, means that every vendor creates its own ecosystem. On top of that comes prevention from attack all the way from information stealing, physical tempering to problems we have not encountered in the pre-IoT world, like denial-of-sleep, synchronization and energy attacks [9], [10], [11]. Since today the IoT infrastructure is centralized and focused on a client/server model, *in fine* all communication needs to go either through mobile networks or the Internet even when the devices are physically close to each other, it is vulnerable to standard Internet attacks as well [12], [13]. Authentication relies on the central server that can be easily compromised. Thus, the model works well for small scale IoT but does not provide sufficient mechanisms for future, large scale IoT projects which incur very high costs.

In order to overcome these issues we will seek to provide an efficiently programmable approach for flexible network management [14] a decentralized approach with peer to peer communication, distributed file sharing and autonomous device coordination, using the latest Blockchain technology[?], a distributed ledger that provides information about data transfers between parties in a secure, publicly verifiable, and efficient way. The properties the technology brings to the system come from the features of the method. By design, a Blockchain is distributed in an anonymous peer to peer network. All transactions (or data transfers) are public, auditable and recorded in blocks that are added to the top of the chain. There is no way to remove anything from a Blockchain, one can only add a modified version of a block. As it is decentralized, there is no authority that can be easily compromised. We plan to use the properties offered by Blockchain technology to help improve the shortcomings of IoT: keep immutable record of the history of smart devices, as well as improve the security and trust of messaging by leveraging smart contracts and cryptocurrencies transactions. This cutting edge technology has been already introduced by some companies in the field of IoT [15], but we plan to seek to improve some of its shortcomings and explore how we can bring it to the standardization bodies.

III. OBJECTIVES OF THE PROJECT

The SerIoT project will address all the aforementioned challenges under a common framework based on the cooperative efforts and prior expertise of a strong interdisciplinary consortium, including the most important European key players in the IoT domain. We bring together star European technology companies such as DT/T-Sys. and ATOS together with highly competent SMEs such as HIS, HOPU, GRUVENTA, HIT and ATECH and world-leading European research organisations such as CERTH, JRC, TUB, ICCS, IITIS-PAN and TECNALIA, and universities such as Essex and TU Berlin, with savvy users such as OASA, Austria Tech and DT/T-Systems.

SerIoT aims to conduct pioneering research for the delivery of an open, scalable, secure and trusted IoT architecture that operates across IoT platforms, which will pave the way for the market uptake of IoT applications across different

domains. Key enabling technologies, including Software Defined Networks, Secure IoT routers, Fog Computing, Analytics for improving embedded intelligence of IoT platforms and devices, Design-driven features for improving both resource efficiency and self-monitoring of next generation of “Things”, will be investigated in SerIoT, emanating from the market and industrial needs [16] for the delivery of safe and reliable IoT connected devices. SerIoT will consider a holistic approach in the formal definition of the end-to-end IoT network ecosystem, considering a multi-layered schema dealing with network, transport layer and perception layers. In this context, SerIoT technology will be installed, deployed and validated in emerging IoT-enabled application areas (i.e. Smart Transportation, Surveillance and Flexible Manufacturing/Industrie 4.0 as core business areas and Food, and Supply Chains) throughout its lifetime, enabling the conduction of pioneer R&D for the delivery of horizontal IoT end-to-end security platform in Europe.

With this overall ambition, the SerIoT project pursues a number of Technical Objectives which are listed below:

- To provide new means to understand the existing and emerging threats that are targeting the IoT based economy and the citizens’ network. To research and analyse how Blockchain and distributed ledgers can contribute to improving IoT solutions. Moreover, to understand how to solve the know issues of IoT and blockchain.
- To introduce the concept and provide the prototype implementation of (virtualized) and self-cognitive, IoT oriented honeypots, easily configurable so as to meet the standards of and adapt to any IoT platform across domains (e.g. embedded mobile devices, smart homes/cities, security and surveillance, etc.) that will be both integrally connected with the core network components and centrally controlled, as well as that will have a transparent function within the network’s total behaviour either it is active or passive.
- To deliver the design and implement the corresponding prototype of smart SDN routers for the dynamic (i) detection of suspicious/high risk paths, (ii) re-planning and (iii) re-scheduling of the routing paths of the transmitted information in IoT networks over secure and (per user or per case-) preferable connections, supporting among others the interference of the human (i.e. semi-supervised approach), when needed. Furthermore, this objective will design and implement a suitable substrate of fog nodes to support secure allocation of compute, storage and network resources for (i) localized processing of sensitive information, (ii) define the security requirements of a path coordinated by SDN, and (iii) enable secure communication with the core cloud.
- To introduce an extra, security dedicated, physical layer to the manufacturing of existing IoT platforms and devices so as to offer a secure-by-design architecture and monitoring capabilities for the sake of the network. To explore introduction of Blockchain as a security and

privacy preserving layer for IoT. Along with improving the shortcomings of the existing efforts devoted to it.

- To optimize the information security in IoT networks in a holistic, cross-layered manner (i.e. IoT platforms and devices, Honeypots, fog nodes, SDN routers and operator’s controller) that will be based both on dynamic and distributed processing of variable complexity by single network components (i.e. IoT platforms, devices and honeypots will perform lightweight processes while fog/cloud nodes and SDN routers will be shouldered with more heavy processes), as well as on a centrally located server/controller that will have the main control of the network and will collect, aggregate and appropriately fuse the transmitted data and produced metadata.
- To utilize and develop the appropriate technologies, so as to implement an efficient and robust Decision Support System (DSS) on the controller’s side, where all data and metadata will be collected, for (i) the detection of potential threats and abnormalities, (ii) including a competent package of comprehensive and intuitive (visual) analytics (i.e. put the human in the loop for reasoning, hypothesis testing and interference in the decision making), and (iii) the generation of escalating mitigation strategies according to the severity of the detected threat.
- To enhance the inter-connection of heterogeneous devices by speeding up the communication processes and by selecting the optimal routing path for the transmitted information in terms of both security and travelling time.
- To introduce a methodology and to provide a tool-chain for automatic generation of design-driven security features monitors and validators for IoT platforms and networks based on IoT architecture and behaviour model specifications.
- To validate the aforementioned actions in both large- and small-scale representative real-case scenarios involving heterogeneous IoT platforms and devices in an EU wide testbed covering Thus, a wide variety of eminent domains.

SerIoT also aims to provide a useful open reference framework for real-time monitoring of the traffic exchanged through heterogeneous IoT platforms within the IoT network in order to recognize suspicious patterns, to evaluate them and finally to decide on the detection of a security leak, privacy threat and abnormal event detection, while offering parallel mitigation actions that are seamlessly exploited in the background. Furthermore, the project will also address the role of networking, and in particular transmission control, media access control, bandwidth allocation, and routing, for anomaly detection and mitigation in the IoT. Thus, the **SerIoT System Architecture** is based on the expected work-flow of the system, broken down into several core architectural elements (see Figure 1).

A. IoT Data Acquisition Platform

This layer is comprised of low-level IoT-enabled components that constitute the distributed IoT infrastructure backbone ranging from IoT platforms and devices, foreseen SerIoT

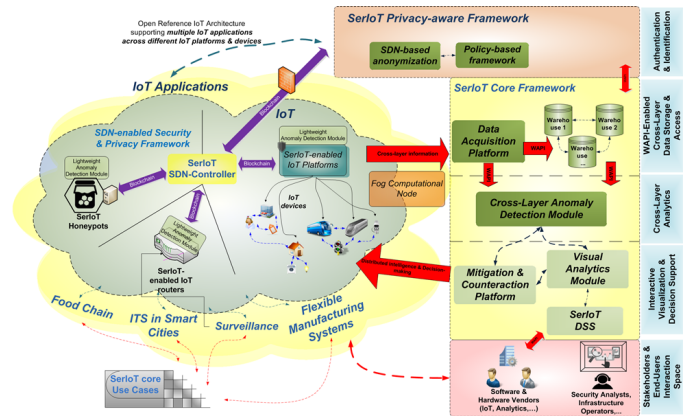

Fig. 1: Overview of SerIoT’s architecture.

fog nodes including honeypots as well as normal computation engines and storage capabilities and the routers enriched with the Software Defined Network (SDN) framework of SerIoT. The SDN framework will use an OpenFlow SDN-Controller that will specify and control routing paths for all given IoT applications. Similarly it will be possible to have specific SDN-Controller specialised to a single IoT application, or to groups of related IoT applications. The SDN-Controller will be a generic piece of software that may be incarnated for different IoT systems and it may be run on a given router for all routers in the SerIoT network, or it may be run remotely, as part of the core cloud or on a specific server. Thus, multiple SDN-Controllers may be running simultaneously for a complex set of IoT applications, even though some or all of the routers are common to some or all of the applications. The potential of smart network management of SDN [17], [18] will be considered for anomaly detection and mitigation.

These components will continuously gather information to feed into the Analytics module (e.g. network activity, attack-related information) in a distributed manner and in this context a modular middleware will be employed building upon on previous successful paradigms (i.e. WAPI API [19]) for the implementation of the SerIoT data collection framework. The framework has been initially developed in WOMBAT project and was further extended in Vis-SENSE and NEMESYS projects [20]. This layer will feed the necessary information needed by the other architectural elements of the distributed SerIoT framework, which will deal with the ad-hoc anomaly detection and the centralized decision support framework, supported by the core cloud. These components will be coupled with innovative visual analytics techniques to further support decision making to the respective operators[?], [21]. In addition to the security monitoring, means for monitoring the energy consumption of the SerIoT network will also be introduced; indeed energy consumption has become an important issue in network in general since it is a significant component of the economic cost system operation, as well as significant from the point of view of CO2 impact.

B. Ad-hoc Anomaly detection Platform

This layer will deal with the design and implementation of a modular information network security component stack, which will support the provision of a number of security mechanisms that will be executed across IoT devices, honeypots and routers. Lightweight techniques fully exploiting the capabilities (single core versus multiple CPU cores) of each IoT device (accessed through the corresponding IoT platform) will be investigated for the identification and prediction of abnormal patterns [22]. Lightweight and robust anomaly detection techniques based on local traffic characteristics such as dynamic changes in queue lengths and second order properties of traffic will be regularly measured and probed by smart probe “cognitive packets” sent out by the SDN controller, feeding into the SDN-Controller’s routing decisions. Analysis of wireless communication links based on research based evidence and performance data will also be used to feed the anomaly detection functions. These smart probe packets will bring back the information to the SDN-Controller’s Cognitive Security Memory (CSM), which will be used for periodic or on-demand routing updates, to eliminate lack of security and points of failure (e.g. intelligently route traffic when an attack has been identified) and bottlenecks stemming from the network intrusion attempts. This data will also be forwarded to the Analytics modules for confirmation (or the opposite), which will in turn come back to the SDN-Controller’s CSM. Any alert at the CSM level that is clearly denied by the Analytics module will be removed, while alerts that are either confirmed or not denied clearly will be acted upon for greater security. Between updates from the Analytics module, the CSM will remain under the influence of the most recent information it has received, although it may not react to this immediately. This may lead to some reactions or re-routing under some false alarms, but the principle followed is that it is better to react than to discover a security breach after it has done its harm.

C. Interactive Visual Analytics and Decision Support Tools

This architectural layer will deal with the interactive decision support tool kits that will be delivered to the end-users (i.e. IoT network operators) of the SerIoT system. It will be composed of advanced information processing mechanisms, fully utilizing the raw measurements from the SerIoT IoT-enabled data collection infrastructure (i.e. devices, routers and honeypots), which will be able to effectively detect potential abnormalities at different levels of the IoT distributed network in the spatiotemporal domain. To support decision making in terms of analysing the root cause of attacks [23] in the IoT infrastructure, a novel visual analytics framework will be researched and developed dealing with the effective management and visualization of data.

D. Mitigation and Counteraction Platform

This component is responsible for orchestrating, synchronizing and implementing the decisions taken by the aforementioned DSS. Apart from a central processing unit, it will

involve specific software on the network components (i.e. SDN routers, honeypots and IoT devices), remotely handled.

IV. OVERALL APPROACH FOR SERIoT

SerIoT has adopted an agile, trans-disciplinary requirement engineering, modelling and design methodology, which includes the following aspects: (i) End-user and stakeholder requirements engineering and refinement, (ii) Architecture analysis and refinement, (iii) IoT-related research and innovation to implement the architecture, (iv) Prototype technical development and integration plus testing, (v) Creating pilot examples in large-scale business oriented applications (OASA and DT), (vi) Multi-level performance evaluation and end-user validation acceptance based on the fulfillment of Key Performance Indicators (KPI), and (vii) Lessons learned and concrete efforts towards standardization and market take-up of SerIoT results.

It is therefore crucial for the successful outcome of the SerIoT project that a clear well-structured methodology be used. Thus, the overall methodology proposed involves five phases:

- 1) Phase One: Framework Design and Preparation (embodied in WP1 and WP2). This phase marks the beginning of the project and includes the identification of state-of-the-art technologies relevant to the project objectives, through existing knowhow of project partners and existing solutions. The output of this phase will be a comprehensive set of requirements, recommendations and guidelines covering all scientific and implementation aspects of the project. It also includes the conception of a business environment that can provide the framework for commercial exploitation of the envisioned framework along with its exploitable products. It involves market analysis, technology assessment, valorisation and business modelling for successful penetration in the emerging market around IoT.
- 2) Phase Two: Technical Development and Innovation (WP3 and WP6). In parallel with Phase One, where the definition of the SerIoT architectural framework takes place, this phase will involve the conceptual design and implementation of the envisioned IoT ecosystem. It includes the development of the architectural elements in accordance with their high-level functional, technical and interoperability specifications. The agile process followed in SerIoT will address in a unified way the whole reference chain, including end-users as well as business scenarios (defined in the previous phase) and system requirements. Thus, allowing for holistic implementation of the envisioned framework and tool sets (SDN-controller and secure router, design-driven self-monitoring of IoT devices, ad-hoc honeypots, cross-layer anomaly detection and analytics, mitigation engine, IoT reference malware warehouse infrastructure, etc). The output of this phase is the effective definition of the SerIoT specifications to operational architectural elements by following a UML based approach and

preparing the groundwork for the transfer of the SerIoT approach to real-world environments.

- 3) Phase Three: Integration and Validation (WP7 and WP8). Once the project reaches this phase after the realisation of the SerIoT prototypes components, the following activities are anticipated: (i) Individual Component/Module Configuration and Adaptation, will take place including experimental verification in the virtual testing environment towards integration into the SerIoT framework. (ii) Prototype integration and iterative testing, in with a specific integration methodology addressing interdependencies, hierarchy, software and hardware implementation, test-bed plans, etc., followed by system integration. Integration should assemble all architectural elements and iteratively deployed into real-life demonstration sites (DT, OASA, etc.).
- 4) Phase Four: Demonstration and Evaluation (WP8). Due to the agile approach we will adopt, this phase will be run almost in parallel with design, development and integration activities, and focus on fine-tuning and validation of the whole framework as well as on the assessment of the demonstration phase of the project. Thus, this phase is concerned with the iterative deployment of the end-to-end IoT framework in the business scenarios of SerIoT (OASA, DT) as well as the overall project evaluation (lessons learned). This should be followed by activities that address follow-up project achievements. Overall activities will include as (i) System Acceptance involving the execution tests, the recording of findings and the addressing of identified shortcomings. Furthermore, laboratory integration tests will be conducted in order to identify potential leaks and bugs of the prototype system prior its deployment and evaluation in realistic conditions. (ii) Validation of the whole system against the user requirement specifications and the developed business and exploitations plans. (iii) Evaluation of the entire project and its foreground along with tangible achievements compared to the initial project objectives, with adequate focus on technical evaluation (i.e. KPIs), user acceptance and impact assessment.
- 5) Horizontal Activities: Project Management, Dissemination/Exploitation and Standardization (WP9 and WP10). This work comprises all the horizontal activities of the project including (i) Overall Project Management (administrative, scientific and technical), (ii) Dissemination and Exploitation of SerIoT results by consortium partners during and after the end of the project, (iii) Standardization activities stimulating seamless connectivity with existing industrial bodies and initiatives in the domains addressed in the project and will be in line with the guidelines from the related standardization bodies and (iv) Sustainability of exploitable SerIoT products, based on a concrete strategy (IoT market analysis ” SWOT, CBA/CEA analysis stemming from Large-scale trials, detailed business plan, etc.).

A. Use Case 1: Surveillance

This Use Case will target the exploitation of the system on multimedia data streaming from surveillance networks and from proprietary sensor networks (e.g. cameras, registration points, etc.), that render valuable “loot” for fraudulent hackers or unauthorized companies or individuals. In this case, sensitive information related to personal data, and protected by privacy legislation, become available in the interconnected IoT and are obtained via unauthorized access and then are forwarded via the rerouting/bypassing of the information on secure paths. This Use Case will be combined with the next one regarding Intelligent Transport Systems in Smart Cities to demonstrate security scenarios in the context of Autonomic Sensor Systems. Examples of such autonomous systems related to SerIoT include critical infrastructures that can effectively monitor external facilities (Athens Pilot Concept I), and the case where embedded intelligence in IoT devices (e.g. placed on parts of a manufacturing system) can automatically notify storage areas and services to improve maintenance planning and worker safety. These are core impacts stemming from the Flexible Manufacturing domain, which SerIoT targets in particular by our partner DT/T-Sys. This Use Case will be also demonstrated through the infrastructure and public services offered by OASA, the largest transport authority in Greece.

B. Use Case 2: Intelligent Transport Systems in Smart Cities

This Use Case focuses on the analysis and definition of security solutions for Intelligent Transport Systems (ITS) integrated in a Smart City where ITS stations can be vehicles, but also mobile persons, other transportation infrastructures, etc. The term ITS refers to the application of Information and Communication Technologies (ICT) to road transportation to support and enhance various applications. The main concept is to integrate computers, electronics, wireless communications, sensors, and navigation systems such as Global Navigation Satellite Systems (GNSS), to enable the collection and distribution of information to and from the vehicles. One of the main standardization activities in ITS is specific to Vehicle to Vehicle communications where generic ITS stations (e.g. cars or a roadside platform) exchange information in a secure way through Dedicated Short Range Communication (DSRC), also called ITS G5 in Europe. A key aspect of such an example of Cooperative-ITS (C-ITS) is the establishment of “trust” between participating systems and devices. The C-ITS security framework (for cars and infrastructure stations) is mainly based on the Public Key Infrastructure (PKI) concept and is currently defined at the EU level in the C-ITS deployment platform.

While the use of PKI for a specific vehicle based ITS application like Collision Avoidance is well defined and described in specification documents, the secure and safe integration of ITS stations in the Smart City and transport systems is still a subject of investigation. We will explore the security framework for such applications beyond the ones prescribed at the EU level, through C-ITS deployment, namely the buses

provided by OASA, and ATECH's contribution of roadside ITS stations. IoT security solutions will be integrated to ensure that the evolution of ITS will not generate security risks or vulnerabilities when different means of communication and devices are integrated. In addition, cyber-physical aspects are quite relevant in ITS and a security breach can generate not only loss of data but also risks to physical safety, including possible loss of life. Thus, the related security requirements will differ from generic IoT security requirements, as the reaction time of the cyber-physical components are very short and the related security solutions must react very quickly.

Two core aspects will have to be taken into consideration: (a) Vehicles and drivers will be connected through multiple wireless technologies such as Cellular Networks, Bluetooth, Wi-Fi, etc. (b) The security of the ITS station and the exchange of information (including personal data) will have to be protected in this heterogeneous context. (c) Beyond cars, people on the streets and other roadside nodes could also be connected to ITS stations. Thus, widening the current concept of ITS station and its collaborative functionalities. This Use Case will also be coupled with the Surveillance Use Case (monitoring of an infrastructure) and will be instantiated in the large-scale IoT-enabled systems that are described below.

1) *Bilbao Pre-Demonstrator and Real World Scenarios:*

This pilot offers an intermediate step between early validation of algorithms in a laboratory environment, and the actual exploitation of the system in real world environments as in the next three use-case pilots. In particular, all applicable systems of the SerIoT solution will be tested in the controlled environment of the Bilbao park before being exploited on the streets of Athens so as to significantly facilitate the early detection of faults, bugs, etc., to minimize any risk to the public, and thoroughly and repeatedly check certain cases with no time restriction or environmental disturbances. The TECNALIA private test track is a fully instrumented permanent test site for Automated Vehicles composed of two Renault Twizy automated vehicles, a private (dedicated) test track with central station (with I-to-V and Vehicle-to-Vehicle communication) and a driving platform simulator. This scenario will help validate some of the individual and cooperative manoeuvres in the vehicles: overtaking, intersection lane change and roundabouts. Dual mode services, such as control of automated functions and sharing techniques between vehicle and driver, can be tested. Technology providers from the consortium will participate in this demonstrator.

2) *Transport for Athens Pilot Concept I:* Audio permanent sensors and cameras will be installed in public transport vehicles and depots to detect illegal or unwanted activities such as window scratch graffiti, graffiti, potential security incidents, and unsolicited activities (such as begging, in-vehicle music playing, etc.). This low-cost network of microphones and cameras, coupled with an "security incident control center", will have the capability to detect selected image frequencies for graffiti and scratch graffiti, and detecting and recognizing sound patterns that indicate security incidents or unsolicited activities. This in-vehicle and depot systems will have capabil-

ities of audio feedback, in order to deter and avert unwanted and illegal actions. The central system will identify the vehicle in which an incident takes place and give the operators required information for incident management.

3) *Transport for Athens Pilot Concept II:* The installation of engine sensors in buses and trolleybuses (potential extensions to Metro will also be investigated during pilot designs), aims to enable the access to engineering data in order to identify potential future breakdowns and create engineering log of required data, in order to plan maintenance activities, using the secure and safe IoT ecosystem of SerIoT.

Both of the "Athens Pilot" Use Cases will be organized by OASA with ICCS and CERTH for the application development and integration in liaison with project partners ATOS, HOPU and DT/T-Sys.

4) *C-ITS Stations Vienna Pilot Concept III:* Use of existing and installed C-ITS stations in a living lab environment with additional security elements of SerIoT for the monitoring of security risks and attacks from the connected sensors and external C-ITS dynamic communication links. Enable and support fast recognition of "insecure ITS stations" or other external users and contribute data reports and logs to the clarification of the "unclear situation" in terms of severity of the risk and the consequences for the extended and distributed C-ITS network (e.g. options could range from closing one network channel of the ITS station, temporarily close the receiving channel, temporarily shut down the C-ITS station, to report to central operators to close all "linked stations" down in "hibernation mode" till certain conditions are met again and operational capacity can be resolved). Generate for the operator additional recommendations and hints for regular network operation and propose improvements for regular and stable operations. ATECH has access to ITS stations in the Vienna Living lab environment and will offer the expertise and resources from there in order to set up the aforementioned scenario.

C. Use Case 3: Flexible Manufacturing Systems

This Use Case will deal with Flexible Manufacturing Systems (Industry 4.0), which concern a sophisticated approach for enabling connected industry to create value and novel business models. This Use Case will provide monitoring and detection of physical attacks to wireless sensor networks in the context of the Industry 4.0 and will be mainly supported by DT/T-Sys. and the testbed provided by UEssex. There will be two concrete scenarios, which will be instantiated in DT/T-Sys. infrastructure:

- Attack on an intelligent automatic warehouse such as those that are planned by Amazon. In this use case the warehouse is operated by wireless connected robots, which collect the purchase lists automatically and bring the goods to the packing stations. Since all data communication is wireless, many attack vectors may be used for breaking or jamming the communication line. Within SerIoT, techniques such as anomaly detection at SDN and

device levels will be utilized for the early identification of such attacks.

- This use case is also an example of dealing with a critical infrastructure, where some of the components, actors or sensors are linked by wireless technology such as W-Lan or Bluetooth. Jamming attacks can disturb the communications, so that the supply of critical resources such as energy or water can be impacted seriously. The monitoring and detection system of SerIoT will be also utilized here to demonstrate the feasibility of mitigating such attacks, and tested in OASA pilots, in DT/T-Sys., and perhaps in other contexts.

D. Use Case 4: Food Chains

Food Chains can illustrate end-to-end security across communication channels, i.e. Transport Layer Security, Datagram TLS protocol, etc., by addressing device authentication mechanisms, the detection and avoidance of DoS and replication attacks, as well as early detection of the interruption of IoT devices (critical functionality), while the requirements related to the mobility of these devices will be explored, for instance when they are deployed in an environment where no protection is available by design. Since many food items are perishable and can only remain in shops for a certain time before they become unfit for consumption, replacing printed “deadlines” by IoT devices on packages will communicate to shop managers when a deadline is reached and flash a red LED indicator for the shop managers and customers, offering “on board sensing and communications” for food. This Use Case will be supported by third parties that will join the SerIoT consortium and interconnected to the project through the EU wide test-bed supported by UEssex.

V. CONCLUSIONS

As we move towards the IoT and the IoE, we are opening our most vital physical systems that support our daily life, to possible security and privacy breaches, and attacks that can impede and impair all of our common daily activities.

Thus, in this paper we have outlined the EU H2020 SerIoT project which addresses the IoT Security Challenge by developing, implementing and testing a generic IoT framework based on a specific adaptation of the concept of smart Software Defined Networks, augmented with secure routers, advanced analytics and user friendly visual analytics. The SerIoT project will create a unique and portable software-based SerIoT network to spearhead Europe’s success in IoT security.

SerIoT has formulated major Scientific and Technological Objectives which will also help us monitor overall progress based on specific quantitative and qualitative indicators relevant to each objectives. These advances will also be evaluated in individual lab test-beds and in an integrated EU wide testbed interconnected and demonstrated via significant use cases by our industry partners.

ACKNOWLEDGEMENT

This research has been supported by funding from the H2020-IOT-2016-2017 (H2020-IOT-2017) Program under

Grant Agreement 780139 for the SerIoT Research and Innovation Action.
